Internet Outage That Crashed Dozens Of Websites Caused By Software Update

Updated July 22, 2021 · 2:22 PM ET

DEEPA SHIVARAM 

A widespread internet outage caused several major websites to shut down Thursday afternoon, including Amazon, Delta, Capital One and Costco.

Akamai, a content distribution network that helps with the spread of data around the internet, posted on [Twitter](#) that a software configuration update caused a bug in its DNS system.

A DNS, or domain name service, helps match a website's name to its IP address. If the DNS fails, it becomes impossible to search and connect to a website by name.

Bad Ubuntu update crashes global Azure Kubernetes services

A flawed Ubuntu systemd update appears to have taken Azure virtual machines running on Ubuntu offline by breaking DNS – causing a significant Azure Kubernetes outage for Ubuntu users.

1/25 **Post Incident Review (PIR) – Azure Networking – Global WAN issues (Tracking ID VSG1-B90)**

What happened?

Between 07:08 UTC and 12:43 UTC on 25 January 2023, customers experienced issues with network connectivity, manifesting as long network latency and/or timeouts when attempting to connect to resources hosted in Azure regions, as well as other Microsoft services including Microsoft 365 and Power Platform. This incident also impacted Azure Government cloud services that were dependent on Azure public cloud. While most regions and services had recovered by 09:05 UTC, intermittent packet loss issues caused some customers to continue seeing connectivity issues due to two routers not being able to recover automatically. All issues were fully mitigated by 12:43 UTC.

How did we respond?

Our monitoring detected DNS and WAN issues starting at 07:11 UTC. We began investigating by reviewing all recent changes. By 08:20 UTC, as the automatic recovery was happening, we identified the problematic command that triggered the issue. Networking telemetry shows that nearly all network devices had recovered by 09:05 UTC, by which point most regions and services had recovered. Final networking equipment recovered by 09:25 UTC.

Russian top-level internet domain suffers massive outage

Russian citizens couldn't access the majority of websites on the country's .ru domain for several hours on Tuesday, including the Yandex search engine, the VKontakte social media platform, the major state-owned bank Sberbank and news outlets.

The outage was **reportedly caused** by a technical problem with the .ru domain's global Domain Name System Security Extensions, or DNSSEC. It appeared to be unintentional, unlike other recent blackouts of Russian internet services, which observers have tied to government intervention.

API, ChatGPT & Sora Facing Issues

Incident Report for OpenAI

Postmortem

Introduction

This post-mortem details an incident that occurred on December 11, 2024, where all OpenAI services experienced significant downtime. The issue stemmed from a new telemetry service deployment that unintentionally overwhelmed the Kubernetes control plane, causing cascading failures across critical systems. In this post, we break down the root cause, outline the steps taken for remediation, and share the measures we are implementing to prevent similar incidents in the future.

Telemetry services have a very wide footprint, so this new service's configuration unintentionally caused every node in each cluster to execute resource-intensive Kubernetes API operations whose cost scaled with the size of the cluster. With thousands of nodes performing these operations simultaneously, the Kubernetes API servers became overwhelmed, taking down the Kubernetes control plane in most of our large clusters. This issue was most pronounced in our largest clusters, so our testing didn't catch it – and DNS caching made the issue far less visible until the rollouts had begun fleet-wide.

The Kubernetes data plane can operate largely independently of the control plane, but DNS relies on the control plane – services don't know how to contact one another without the Kubernetes control plane.

In short, the root cause was a new telemetry service configuration that unexpectedly generated massive Kubernetes API load across large clusters, overwhelming the control plane and breaking DNS-based service discovery.

current scheme: subject number tells you something about
the topic (nearby numbers are in similar areas of EECS)

why four digits after the 6? the registrar doesn't allow a department to reuse a permanent subject number for a new class within five years. solution: create a new three-digit based scheme, append 0's to make then four digits. after five years, revert back to three digits.

modularity and **abstraction** mitigate complexity.
a **client/server model** allow us to enforce
modularity by putting modules on physically
separate machines.

modularity and **abstraction** mitigate complexity.
a **client/server model** allow us to enforce modularity by putting modules on physically separate machines.

naming is what allows modules to interact, and can help us achieve other goals through properties such as indirection, user-friendliness, etc.
